Snake bite poisoning

A twelve years retrospective analysis of telephone calls reported to the National Poisons Information Centre, AIIMS

Department of Pharmacology, AIIMS, New Delhi
Snake bite is a major environmental and occupational hazard in rural India and South Asian region.

India has one of the highest rates of death from snake bite in the world.

WHO has estimated the highest number of snake bites (83,000) and deaths (11,000) per annum in India.

80% of snake bite victims in most of the developing countries seek traditional remedies before visiting a health care facility. This has resulted in high mortality.
Epidemiology

- As per few reports there are cases of approximately 200,000 bites and 35,000-50,000 snake bite deaths
- No reliable national data available
- High occurrence of snake bite reported in the states of Uttar Pradesh, Andhra Pradesh, Tamil Nadu, Kerala, and Maharashtra
- Incidences of snake bites are twice in male then female
- Majority of the bites are on the lower extremities
- 50% of bites by venomous snakes are dry bites that result in negligible envenomation

Department of Pharmacology, AIIMS, New Delhi
Snake bite mortality in India: Study by Mohapatra et al (2011)

High incidence states (Annual snake bite deaths) -

Uttar Pradesh: 8,700
Andhra Pradesh: 5,200
Bihar: 4,500

Department of Pharmacology, AIIMS, New Delhi
Classification

- Worldwide, only about 15% of the more than 3000 species of snakes are considered dangerous to humans.
- The family Viperidae is the largest family of venomous snakes, and members of this family can be found in Africa, Europe, Asia, and the Americas.
- The family Elapidae is the next largest family of venomous snakes.
- There are around 216 species of snakes in India, out of which 52 are recognized as poisonous.

Traditionally big four include:
1. Elapidae (cobra and Krait)
2. Viperidae (Russell’s and saw scaled viper)

Other snakes of medicinal significance— King cobra, monocle cobra, Asiatic cobra, Andaman cobra, saw scaled viper of northern India and the Hump nosed viper from Kerala.
Common Indian snakes

- Cobra (Naja naja)
- Common krait (Bungarus caeruleus)
- Viperidae
  - Russell's viper (Daboia russelii)
- Saw-scaled viper (Echis carinatus)
    (Hump-nosed pit viper (Hypnale hypnale))
Common Indian snakes: Characteristics

**Cobra**
- Head of cobra is not distinct from neck which is dilatable and hood bears a binocellate mark on upper side.

**Krait**
- The fangs are short and fixed. Steel blue coloured hexagonal scales on dorsal side with rows of paired white stripes across belly.

**Vipers**
- Large mobile fangs which are canalized and retractable
- Russell’s Viper is brown in colour, elliptical patches in three rows on body
- Triangular head with prominent nasal opening
- Pit viper is uncommon in India

**Sea Snakes**
- Short mobile fangs
- Compressed posteriorly and has a flat tail
Who are at risk?

- Agriculture
- Ecotourism
- Fishermen
- Dealing with venom
- Hunters

Department of Pharmacology, AIIMS, New Delhi
### Common Indian snakes bites: Characteristics

Snake venom has different predominant effects depending on the family:

- **Elapidae**
  - Neurotoxic
  - Cardiotoxic
  - Nephrotoxic

- **Viperidae**
  - Hemotoxic
  - Necrotoxic

- **Crotalidae**
  - Necrotoxic

Department of Pharmacology, AIIMS, New Delhi
April 1999 – March 2011: Total calls 13,162 telephone calls, snake bite cases=290

Eight groups:
- Household products
- Agricultural pesticides
- Drugs
- Industrial chemicals
- Plants
- Bites and stings
- Miscellaneous
- Unknown groups

Calls from Delhi - 71.35%
Calls from other states of India - 28.65%

- Adults involved - 77.66%
- Children involved - 22.33%
- Age group with the highest incidence of reporting was between 18-40 years (82.53%)
- Males outnumbered females (M=73.10%, F= 26.89%)

Department of Pharmacology, AIIMS, New Delhi
Incidence of snake bites

- Cobra and Krait: 83%
- Vipers: 9%
- Unidentified: 3%
- Non-poisonous: 5%

North India: Elapids
South India: Viperidae

Department of Pharmacology, AIIMS, New Delhi
Site of snake bites

- The victims were bitten mostly at night or midnight:
  - **Nights**: 58.73%
  - **Daytime**: 41.26%

- A significant number of cases occurred while the victims were asleep.
Incidence of snake bite varies with climate...

- Peak in July, August and September
- No bites in December, January and February

Department of Pharmacology, AIIMS, New Delhi
## Clinical Presentation

Department of Pharmacology, AIIMS, New Delhi
Medical aid received

- The time interval:
  - Within 1-4 hours: 51.77%
  - After 4 hours: 48.22%
  - Antivenom received: 71.25%

- Most of patients received 17-20 vials of Polyvalent anti-snake venom (ASV)
- Two patients were given 140 ASV vials
- One patient was given 350 vials of ASV over 10 days without any clinical improvement
Summary of data

- Majority of the snakebite cases were due to Cobras and Kraits
- Increased incidence of bites during Rainy/Monsoon season
- High incidence of bites reported at night
- Males outnumbered females (M= 73.10%, F= 26.89%)
- Highest incidence reported between 18-40 years
- Incidence of bites in lower extremities was high (50%)
- Sign of local envenomation was predominant, with pain (57.14%)
- Early administration of antivenom reduced the risk of complications
- The limitation of this study was the data collected from telephonic calls.
- We do not have the prognosis of the snake bite cases reported to the respective hospitals

Department of Pharmacology, AIIMS, New Delhi
Management - Pre Hospital

- Keep the victim calm
- Wash the bite site with soap and water/wound should clean with antiseptic
- Immobilize the bitten area
- Do not cover the bite area and puncture marks

What not to do?
- No cryotherapy
- No incision at the bite site
- Do not burn the wound
- Do not suck the wound with mouth
- Potassium permanganate should never be used

Department of Pharmacology, AIIMS, New Delhi
Hospital & Antivenom Therapy

- Maintain airway, breathing and circulations
- Oxygen supplementation
- Intravenous fluid
- Vasopressors for hypotensive shock
- Antihistamines anaphylactic reactions
- Analgesics alleviate pain
- Antibiotics and antitetanus

**Investigation**

Blood samples for total blood count, coagulation profile, serum biochemistry renal and hepatic functions
20WBCT
ASV reactions  Early Anaphylactic reactions & Anaphylaxis  (10-180 min)

Department of Pharmacology, AIIMS, New Delhi
Anti-snake venom (ASV) is the mainstay of treatment

- **ASV is produced both in liquid and lyophilized**
  - *liquid ASV requires a reliable cold chain and has 2-year shelf life.*
  - *Lyophilized ASV, in powder form, has 5-year shelf life and requires only to be kept cool.*

- No monovalent ASV
- Polyvalent ASV is Questionable?
- Humpnosed pit viper (Hypnale hypnale)
- Saw-scaled viper (Echis carinatus sochureki)

Department of Pharmacology, AIIMS, New Delhi
Administration of antivenom

- Freeze-dried (lyophilised) antivenoms are reconstituted, usually with 10 ml of sterile water. The freeze-dried protein may be difficult to dissolve.

- Skin and conjunctival “hypersensitivity” tests may reveal IgE mediated Type I hypersensitivity to horse or sheep proteins but do not predict the large majority of early (anaphylactic) or late (serum sickness type) antivenom reactions. Since they may delay treatment and can in themselves be sensitizing, these tests should not be used.

Epinephrine should always be drawn up in readiness before antivenom is administered.

Antivenom should be given by the intravenous route whenever possible.
Constraints in management of snake bite

Problem in management
- Superstitions surrounding snake bites, apprehension and terror towards non-traditional medicine
- Time wasted in going to traditional/local healers
- Lack of awareness among people for seeking early medical help

Availability of ASV reduces the bite to needle time
- Sensitized early administration of ASV results in better outcomes
- ASV neutralizes circulating snake venom, as while time elapses more and more, venom is bound to the target tissues becoming less amenable to neutralization by ASV.
Present Scenario

• Rural people trust herbal and other traditional forms of treatment
• Traditional practitioners are readily available in the village and their services are cheap
• About 50% of bites by venomous snakes result in envenoming (injection of sufficient venom to cause local and/or systemic effects) even useless remedies will appear effective in a proportion of cases.

However, these treatments have no scientifically demonstrable effectiveness, may be harmful and will delay the patients’ arrival in hospital.

Alternative therapies should therefore be discouraged or the traditional practitioners educated to refer patients with definite symptoms of envenoming.
Some important points

- NPIC works round the clock to provide its services
- Awareness in the local population on providing first aid to snake bite
- Local healers/tantriks/ojhas should be avoided in snake bites cases
- Peripheral doctors should be trained on the diagnosis and management of snake bite use of anti venom
- In absence of symptoms, victim should be observed for at least 24 hours

Country wide epidemiological picture can’t be drawn due to non existence of central registry of cases
Prevention

- Community education is the key to reducing the risk of snake-bite.
- Encourage safer working and walking by using adequate footwear.
- Avoid walking through knee high grass.
- Wear leather ankle shoes for outdoor activities.
- Protective clothing and carrying a light after dark.
- Safer sleeping by using a well tucked-in mosquito net.
- Victims of bites are encouraged to travel to hospital without delay.
- Not wasting time with traditional treatments.
